**Abstract**

7 Two non-destructive sexing techniques, suitable for use in the field, are described  
8 for the Warren rootcollar weevil *Hylobius warreni* Wood (Coleoptera:  
9 Curculionidae). On the 2<sup>nd</sup> visible abdominal sternite of males, there is a  
10 longitudinal depression which is absent on females. In addition, hairs on the last  
11 visible abdominal sternite of females are arranged longitudinally, while hairs on  
12 males are arranged radially. Accuracy for the first character was 90%, and sex  
13 could be determined without the aid of magnification. The latter character was  
14 slightly more reliable with a 95% accuracy, but required some magnification.

15

16 **Keywords** *Hylobius warreni*, sex determination, sexual dimorphism, Warren  
17 rootcollar weevil

**Résumé**

19 Deux techniques non destructives, permettant le sexage lors d'une étude de  
20 terrain, sont décrites pour le charançon de Warren *Hylobius warreni* Wood  
21 (Coleoptera : Curculionidae). Sur le 2<sup>ème</sup> sternite abdominal visible des mâles, il y  
22 a une dépression longitudinal qui est absente sur les femelles. De plus, les soies du  
23 dernier sternite abdominal visible, sont placées longitudinalement sur les  
24 femelles, tandis que les soies des mâles sont placées radialement. La fiabilité du  
25 premier caractère est de 90% et le sexe peut être déterminé sans l'aide d'un  
26 grossissement. Le dernier caractère mentionné est légèrement plus fiable avec une  
27 exactitude de 95% mais nécessite un grossissement.

28 **Mots clés** *Hylobius warreni*, détermination du sexe, dimorphisme sexuel  
29 charançon de Warren

30

31 The Warren rootcollar weevil, *Hylobius warreni* Wood (Coleoptera:  
32 Curculionidae), is distributed widely throughout the boreal forest in Canada,  
33 where it attacks several conifer species (Wood 1957). Live, healthy trees are  
34 susceptible to attack from *H. warreni* from a young age (Cerezke 1970). Larvae  
35 feed on phloem in the root and root collar region of their host trees. This may  
36 predispose trees to infection by root and stem diseases, and in young trees it may  
37 cause complete girdling, killing the tree (Warren 1956, Cerezke 1970).

38  
39 Widespread regeneration of the main host in British Columbia, lodgepole pine  
40 (*Pinus contorta* var. *latifolia*) has led to increasing incidence (Schroff et al. 2006),  
41 and hence a renewed interest in this insect. Behavioural and ecological research  
42 on *H. warreni* could benefit from an in-field, non-invasive sexing technique, but  
43 no. No reliable technique is non-invasive techniques are available, even though  
44 the external anatomy of the weevil has been described in great detail (Wood  
45 1957, Warren 1960). Thus, the Invasive techniques that do not involve sacrificing  
46 insects include identifying apodeme genital tissues in females, which may be  
47 observed by examining the anal opening with fine tweezers. Similarly, gender  
48 may also be determined by observing differences in the relative orientation of  
49 internal markings on the 8<sup>th</sup> sternite (Hopkins et al. 2008). The aim of this study  
50 was to use non-invasive techniques to identify external sex-specific characters  
51 that are reliable and convenient to use in the field.

52

### 53 **Materials and methods**

54 Adult weevils used for the study were caught in a heavily infested plot of planted,  
55 8-year old lodgepole pine in the city of Prince George, British Columbia. Adult

56 weevils for this study were captured in a novel stem trap (Björklund and  
57 Lindgren, in prep) when they ascended trees for feeding. The traps were emptied  
58 on 22 June and 11 July 2006 and weevils were stored in a freezer for later  
59 examination.

60

61 Sexual dimorphism of *H. warreni* was assessed by examining a number of sex-  
62 determining external characters previously used for sexing other species. The  
63 following characters were assessed: The length of the snout (examined for  
64 *Anthonomus grandis*, Sappington and Spurgeon 2000) and the pronotum;  
65 presence/absence of any thorns on tarsal claws (Anthonomine, Kovarik 1983);  
66 the density, length and arrangement of scales on metasternum (*Euscepes*  
67 *postfasciatus*, Baba and Yoneda 2000); a convex abdomen for females and a  
68 saucerlike depression in last sternite for males (*H. abietis*, Anonymous 1952, and  
69 *H. radialis*, Wilson 1966); the arrangement of hairs on the last abdominal sternite  
70 (the scolytine genus *Hylastes*, Grocholski et al. 1976); and longitudinally  
71 depressed abdominal sternites (present to some degree in males of all North  
72 American *Hylobius*, Wilson 1966, and in the Cacao weevil borer *Pantorhytes*  
73 *szentivanyi*, Hassan 1973).

74

75 Weevils were examined under a stereomicroscope at 16× magnification. As a first  
76 step 20 weevils were examined for each of the above characters. As a second step,  
77 promising characters were examined on an additional 80 weevils. After  
78 examination of the characters mentioned above, the weevils were dissected under  
79 a stereomicroscope at 6.4× magnification to determine their sex based on male- or  
80 female genitals (Nordenhem 1989), and the accuracy of sex classification using

81 these characters were established. Each weevil was marked with a unique label  
82 allowing us to cross reference the different techniques.

### 83 ***Results and Discussion***

84 The overall sex ratio as determined by dissection was 40/60 male/female. Due to  
85 the broad overlap between males and females it was not possible to determine the  
86 sex based on the length of the snout (females, N = 14, average = 2.94 mm, range  
87 = 2.50 - 3.20: males, N = 6, average = 2.84 mm, range = 2.60 - 3.05) or the  
88 pronotum (females, N = 14, average = 3.70 mm, range = 3.20 - 4.35: males, N =  
89 6, average = 3.64 mm, range = 3.20 - 3.90). Furthermore, males and females did  
90 not differ with respect to the presence or absence of tarsal claw thorns or the  
91 density, length or arrangement of scales on the metasternum. The presence of a  
92 convex abdomen was not a reliable female character of *H. warreni*, since an  
93 overlapping gradient between the sexes made it impossible to classify the sexes as  
94 either convex or concave.

95

96 Two characters were found that would be useful for separating the sexes of *H.*  
97 *warreni* (Table 1): (1) on the 1<sup>st</sup> visible abdominal sternite there is a longitudinal  
98 depression which in males continues without interruption to the 2<sup>nd</sup> sternite,  
99 forming a sulcus along the midline (fig. 1); and (2) on the last abdominal sternite  
100 the hairs of females are arranged longitudinally, whereas hairs on males are  
101 arranged radially (fig. 2).

102

103 Ninety out of 100 weevils were sexed correctly based on the presence or absence  
104 of the longitudinal depression on the 2<sup>nd</sup> sternite. Some of the females had a small  
105 round depression on the 2<sup>nd</sup> sternite not to be mistaken for the longitudinal

106 depression. This character was best seen when tilting the weevil underneath a  
107 light spot without any use of magnification. Ninety-five out of 100 weevils were  
108 sexed correctly based on the longitudinally or radially arranged hairs on the last  
109 sternite. Many of the females also had a few radially arranged hairs on the last  
110 sternite, thus, to classify a weevil as a male the hairs have to be radially arranged  
111 in more than one row of hairs. Ninety out of ninety-three weevils (97 %) were  
112 sexed correctly based on combining the two methods and exclude weevils where  
113 the male/female identification did not agree between the two.

114

115 Since it is possible to see the longitudinal depression on the 2<sup>nd</sup> visible abdominal  
116 sternite of *H. warreni* without magnification this method can be used in the field  
117 for convenient sex determination with a reasonable accuracy. If a higher accuracy  
118 is necessary it would be better to view the weevils with at least a 12×  
119 magnification to view the orientation of the hairs on the last visible sternite.

## 120 ***Acknowledgement***

121 Carole Brendel is acknowledged for translating the abstract to French, B. Staffan  
122 Lindgren for language editing and suggestions, and Åke Lindelöw for the  
123 suggestion to look at the hairs on the last sternite.
