## 1 **Abstract**

2           The provision and administration of high quality urban public green spaces intertwines  
3 issues of planning, design, management and maintenance with governance. The benefits of such  
4 spaces are often tied to social justice, public health and recreation, biodiversity and helping cities to  
5 deal with climate change. International policies and changes in public administration have  
6 encouraged user participation across multiple phases of green space development. Although sceptics  
7 towards participation are easily found supporting arguments sometimes stand without critique, not  
8 questioning how participation affects the physical quality of green spaces. This literature review  
9 surveyed empirical scientific studies seeking to answer the following research question: How does  
10 research to date reflect over user participation's contribution to public urban green space quality?  
11 The review includes 31 articles from peer-reviewed scientific journals and finds an array of  
12 arguments used to support and attribute potential benefits to participation. However, analysing  
13 what has been empirically tested in these articles shows an even and general lack of proof for these  
14 arguments, implying that many arguments for participation are taken for granted. A particularly large  
15 disparity was found between the discussing and testing of many arguments regarding how  
16 participation may *directly* benefit urban green spaces. Rather than assessing the physical outputs of  
17 participation, most of the empirical studies tested process benefits to users and administrators. Due  
18 to the discovered predominance of these process-driven studies, it remains unclear whether  
19 participation actually improves green spaces, or if it is just for the benefit of the people involved. The  
20 gap in scientific knowledge found here calls for a re-focus to case level research, empirically testing  
21 where the actual benefits of participation lie and how participation processes might best lead to high  
22 quality green spaces in practice.

23 **Keywords:** management; place-keeping; place-making; planning; public involvement; quality

## 24 **Introduction**

25           The provision and administration of high quality public green spaces in cities and  
26 towns is a practical realm that intertwines issues of planning, design, management and maintenance  
27 with governance. The benefits of such spaces are often tied to social justice, public health and  
28 recreation, biodiversity and helping cities to deal with climate change (e.g. Thompson, 2002;  
29 Konijnendijk et al., 2013). Such benefits link these spaces significantly to contemporary city planning  
30 goals for sustainability, particularly as planning thought has developed since the Brundtland  
31 Commission's (1987) definition of sustainability. Subsequent international policies, such as the  
32 Agenda 21 action plan (UNCED, 1992) and the EU's Aarhus Convention (Stec et al., 2000) have been  
33 characterized by the general goals of balancing economic, social, and natural equity. However, the  
34 priorities and implementations of such initiatives vary a great deal with local context (Voisey et al.,  
35 1996), allowing for multiple interpretations of sustainability that guide green space administration.  
36 More recently, many of these ideals have been elaborated into separate, but similarly future-  
37 oriented, lines of thought including resilience thinking and ecosystem services – focusing on benefits  
38 to current and future user well-being and environmental performance (Tzoulas et al., 2007). Despite  
39 similar scope, the multiplicity of priorities and practices within green space administration remains as  
40 an onus upon researchers who seek to evaluate results against intentions and products against  
41 practices.

42           Different experts define public urban green spaces through their own academic or  
43 practical orientations, priorities, and goals - resulting in plurality and complexity in any attempt to  
44 define green space "quality", (Lindholst et al., In press). Adding to many expert voices are those of  
45 the people; one of many takeaways from both Agenda 21 and the Aarhus Convention has been the  
46 goal of bringing citizens closer to the places and services they use. Including the voices of users in  
47 governance, planning, and even design and management processes adds to the complexity. Asides  
48 from civic involvement in the early planning phases for green spaces (e.g. Loures and Crawford, 2008;

49 Tortzen, 2008; Van Empel, 2008), some localities have further delved into sustainability goals by  
50 developing programs where citizen-users physically take part in ongoing maintenance (e.g. James,  
51 2003; Delshammar, 2005; Speller and Ravenscroft, 2005). Distinguished as *civic* and *physical*  
52 *participation* respectively from this point forward in this article, these forms of involvement integrate  
53 users with the series of professions that are responsible for the provision and sustainment of quality  
54 green spaces.

55           Through inclusion of the people in voice or action, green space governance meets  
56 theory from deliberative democracy and communicative planning. Today, such participation is  
57 promoted across multiple phases of green space development. Leroy and Arts (2006) described how  
58 roles and responsibilities have changed during the past decades – environmental governance is no  
59 longer purely government-dominated, but also involves civic society, as well as the market. This has  
60 resulted in a range of new associated interactions, institutions and practices - all of which vary  
61 greatly with context and thus question general or universal conceptual assumptions about  
62 participation. Both supporters and sceptics of participation are easily found in the academic debate –  
63 proponents cite bettered solutions through participation while counterarguments stress downsides  
64 such as inefficiency due to multiple stakeholders, highly varying perspectives and insufficient  
65 knowledge bases (Van Herzele et al., 2005b). The breadth of this debate illuminates the range in  
66 opinion possible over what characterizes, and which practices result in successful participation,  
67 compounding the question of what makes quality green spaces. Together these questions define a  
68 complex, but growing field for evaluative research.

69           Research can provide an unbiased platform to empirically test and form  
70 understandings of participation processes, testing theory and policy against actuality, context, and  
71 practical implementation. However, due to the number of academic perspectives and practical views  
72 on participation, the field remains at risk of inconsistent methodology and reinterpretation of  
73 findings without consideration to context. Thereby, the sometimes uncritical popularity of

74 participation can combine with disparate goals for public urban green spaces to form a potentially  
75 weak, subjective foundation for grounding empirical studies. Even as early as the 1960s, Sherry  
76 Arnstein (1969) warned that participatory processes applied blindly become “empty rituals”, and  
77 need to be evaluated by citizens’ actual effect on process output. Amidst all of this complexity, an  
78 overview is needed of research-to-date in order to benchmark and assess knowledge, trends, and  
79 gaps regarding participation’s outputs in relation to green spaces.

## 80 ***Research questions***

81 This survey of empirical scientific studies seeks to answer: How does research reflect  
82 over user participation’s contribution to public urban green space quality? To answer this, three sub-  
83 questions are employed, the significance of which are explained in further detail in the next  
84 subsection.

85 A. What types of participation are in focus in the research? The types found will be analysed in  
86 terms of which phase of green space development they contribute to. Phases of green space  
87 development in this article are categorized by the *making* phase - where green spaces are  
88 planned, designed and constructed - and the *keeping* phase - or the ongoing work of  
89 management and rehabilitation of existing green spaces, including maintenance operations  
90 and systemic park policy making.

91 B. What arguments are used to support user participation in green spaces? These arguments  
92 will be analysed in terms of which dimension of green space development they support  
93 (users, administration, or green spaces) following Randrup and Persson’s (2009) ‘park-  
94 organization-user model’.

95 C. What empirical evidence exists in the reviewed articles for arguments linking user  
96 participation to green space quality? This will be analysed through the same model as

97 question B to compare results from the reviewed research against rhetoric, focused primarily  
98 upon the dimension of green space development.

### 99 ***Definitions and background to the analysis***

100 Green space development can be understood as the arena where participation  
101 processes can affect green spaces. Developing this thought through definitions in the following  
102 subsections explains the selection of analytical framework for this literature review.

#### 103 User Participation

104 The concept of participation may be understood through many terms, but the  
105 important signifier here is *user* – demonstrating a localness of the target group. *Users* are the people  
106 or groups who regularly or potentially inhabit and interact with a space, a specific part of the public.  
107 With this article’s focus on publicly accessible spaces, *public participation* is a general starting point  
108 to discuss user participation. *Public participation* and *public involvement* are often used  
109 interchangeably, but hold different nuances (Väntänen and Marttunen, 2005). Whereas the term  
110 *public involvement* includes the public in decision making without necessarily guaranteeing effects  
111 upon the end result (World Bank, 1993), Arnstein (1969) stresses that *participation* should give  
112 access to process as well as an amount of power to affect outcomes. The use of these terms as  
113 synonyms shows that participation notions then can range from consultation without influence on  
114 decision to integrated cooperation (World Bank, 1993) – a span that opens scholarly debates over  
115 process, outcome, and participation ideals.

116 Both *participation* and *involvement* can be seen as attributes to the concept of *civic*  
117 *engagement*, which the World Bank (2013) defines as

118 “the participation of private actors in the public sphere, conducted through direct and  
119 indirect interactions of civil society organizations and citizens-at-large with  
120 government, multilateral institutions and business establishments to influence

121 decision making or pursue common goals. Engagement of citizens and citizens'  
122 organizations in public policy debate, or in delivering public services and contributing  
123 to the management of public goods, is a critical factor in making development policy  
124 and action responsive to the needs and aspirations of the people and potentially of  
125 the poor.”

126 This definition further distinguishes between what this paper terms as *civic participation* and *physical*  
127 *participation* - a distinction that holds important implications regarding how directly participants  
128 might influence green space quality. Physical participation can directly affect a green space while  
129 civic participation typically requires additional implementation steps. Examples of these in respect to  
130 the making and keeping of green spaces are provided in Table 1.

131 Table 1 here!

### 132 Public urban green spaces

133 *Public urban green spaces* are defined as openly accessible areas with individual trees,  
134 smaller designed sites and larger nature-like settings in connection to built-up areas, as typically  
135 distinguished within public space (Carmona, 2010) and green space management literature (Dunnett  
136 et al., 2002; Randrup and Persson, 2009). Dunnett et al.’s (2002) report on improving urban parks in  
137 the UK explains that the term *urban green spaces* connotes more than individual *parks*, gardens and  
138 playgrounds, thus opening *urban green* discussions to street trees and less categorized spaces that  
139 are often included within *green infrastructure* (Lafortezza et al., 2013) or *urban forestry* (Randrup et  
140 al., 2005).

141 The words *public*, *urban* and *green* connote significant spatial quality aspects when  
142 assembled. *Green spaces* are particularly rare in *urban*, built-up areas and particular administrative  
143 challenges emerge due to *public* use. Typically characterized by unsealed, permeable, ‘soft’ surfaces  
144 such as soil, grass, shrubs and trees, *green* can be understood in contrast to the *grey spaces* that

145 characterize much of built-up areas - those predominantly sealed, impermeable, 'hard' surfaces such  
146 as concrete, paving or tarmac (Dunnett et al., 2002). The ecological implications of this contrast has  
147 demonstrated green spaces to be of particular importance to cities for potential societal, economic,  
148 health and environmental benefits (Konijnendijk et al., 2013).

#### 149 Green space quality and place-keeping

150 For cities to reap the ecological benefits of green spaces, the "delivery of space  
151 quality" is vital for keeping them from deterioration and malfunction (Carmona et al., 2008, p. 8). Yet  
152 question, complexity and subjectivity remain within the concept of green space quality (Lindholt et  
153 al., In press). Green space quality can neither be summarized into a universal definition nor assessed  
154 by a singular model or assessment tool. How quality is assessed depends upon what type of quality is  
155 in focus, who decides upon it and for whom it is intended. An important question is whether green  
156 space quality should be assessed objectively by experts or subjectively and perception-based by the  
157 public. A combination of the two has been promoted for user-focused quality assessments of the  
158 built environment (Dempsey, 2008), of urban environmental quality (Pacione, 2003) as well as of  
159 visual landscape quality (Daniel, 2001). Quality can have different assessment implications at  
160 different urban scales, since different details come into focus when considering, for example, the  
161 quality of an individual garden or an entire neighbourhood (Dempsey, 2008). On one hand, one  
162 might judge quality with an ecological focus and interest in plant primary productivity, defining urban  
163 green space quality as *level of vegetation cover* and *tree-cover* (Davies et al., 2008). On the other, the  
164 user-centred, subjectivist paradigm of landscape quality assessment regards quality as a production  
165 of the mind rather than physically inherent in the landscape, thereby defining quality based on  
166 interpretation through memories, associations, imagination and symbolism (Lothian, 1999). As this  
167 review encompassed articles of varying scales and perspectives, this article holds a mid-range  
168 definition of green space quality. Guided by the research question of user participation's contribution  
169 to public urban green space quality, i.e. influence upon *physical* green spaces, the definition of  
170 quality for this article includes objectively testable, physical aspects of ecological and user

171 functionality, including the range of ecosystem services that users may appreciate - how the green  
172 space performs environmentally and meets local needs for use.

173           Despite many perspectives on green space quality, the processes and actors  
174 responsible for its delivery have been succinctly compiled and framed in literature on *green space*  
175 *management* (Randrup and Persson, 2009) and *place-keeping* (Dempsey and Burton, 2012). These  
176 realms illuminate the complexity of actors involved in public urban green space development.  
177 Dempsey and Burton (2012) coined the term place-keeping with the purely user-based definition of  
178 green space quality in that quality spaces are those which users want to “visit again and again”.  
179 While differing from the physical green space quality focus of this review, the place-keeping concept  
180 emphasizes the important, ongoing time-aspect of green space development. They further name the  
181 interrelated dimensions of place-keeping which should be taken into consideration in both the  
182 making and keeping of green spaces to ensure sustained quality - namely Partnerships, Policy, and  
183 Governance as well as Funding, Evaluation and Design & Management (Dempsey and Smith, 2014).

184           More aligned with assessing physical green space quality, in green space management  
185 literature, Randrup and Persson (2009) offer a ‘park-organization-user model’, framing three  
186 dimensions - “users”, “managers”, and “urban green environment”. The diagram in Fig. 1 was  
187 adapted from their model for this review by re-clarifying the three dimensions as *users*,  
188 *administration*, and *public urban green space*. Herein, the type of green space was specified and the  
189 management actors were broadened to administrators to encompass any potential participation  
190 initiators. *Administrators* or *administrative actors* here refer to actors potentially receiving input  
191 from participation processes, ranging from regional administration actors to local park maintenance  
192 workers – most often meaning municipal entities with responsibility over green space development,  
193 i.e. the making and keeping of green spaces. The original framework held a one way vector from  
194 green space to (i.e. benefiting) users, demonstrating an instrumental or representative democracy  
195 stance to green space management where only the administration provides services towards high

196 quality green spaces for users (Molin, 2014). The adaptation adds a vector to recognize that users  
197 can also directly impact green spaces through physical participation, thereby updating the model to  
198 include new modes of governance, such as place-based approaches, that are present in  
199 contemporary urban green space development (Ibid.).

200           The division of *physical* and *civic* types of participation, mentioned in the introduction  
201 of this article, can be charted on this adapted framework - highlighting respectively the difference  
202 between processes involving the actual green spaces and interactions primarily between the  
203 administration and users. Charting research findings and propositions along this framework will  
204 relate aspects of participation to green space administration dynamics, allowing the analysis of which  
205 dimension of green space development the participation research has focused upon.

206 Fig. 1 here!

## 207 **Method**

208           To understand how research to date has linked participation with green space quality,  
209 a literature review was designed with the aim of seeking an overview of relevant empirical work.

### 210 ***Search terms and test searches***

211           The definitional ambiguity and many synonyms for the terms *participation* and *urban*  
212 *green space* demanded testing a range of search terms to exclude as few relevant articles as possible.  
213 Initial trial searches for literature demonstrated that *participation*, *involvement*, and *engagement* are  
214 often used interchangeably despite the theoretical nuances previously described. As the inclusion of  
215 each significantly increased the number of search hits, all three were determined important.

216           Initial searches also demonstrated a lack of consistent terminology for referring to  
217 urban green spaces. Terms and keywords used could be case-specific, referring to *parks* or *urban*  
218 *forests*, or more systemic at a larger spatial scale referring to *urban forestry* or park systems in *green*

219 *infrastructure*. Trial and error revealed much higher and more relevant ‘hit’ numbers when each of  
220 the terms *park* and *urban forest* were added to *green spaces*, while *green infrastructure* did not  
221 contribute new hits after adding these terms to those regarding participation. The word *urban* was  
222 intentionally dropped from *urban green space* during the search term definition due to potential  
223 synonyms and alternate wording (i.e. city, town, etc.), so the urbanity of green space type became a  
224 significant limiting factor during the initial manual screening of the search hits for relevancy.

225           Following several trial searches, a string that would include all possible combinations  
226 of the following terms was deemed most encompassing: [‘participation’ OR ‘involvement’ OR  
227 ‘engagement’] AND [‘green spac\*’ OR ‘park\*’ OR ‘urban forest\*’]. Although we feel that the selected  
228 search terms served the purpose of this review and helped provide a sound overview of relevant  
229 literature, we are aware that adding additional search terms could have generated additional  
230 articles. However, a review article is always a balance between research questions asked, the scope  
231 of the literature, and available time and resources.

232

### 233 ***Limiting the literature search***

234           With inspiration from systematic literature review methodology, this review sought quality  
235 articles which could illustrate multiple perspectives within the research theme (Petticrew, 2001;  
236 Guitart et al., 2012; Roy et al., 2012). Systematic review methods ideally encompass an exhaustive  
237 search of all databases and sources published or unpublished on a topic (Petticrew, 2001), but the  
238 breadth and abstractness of this topic’s key concepts forced an amount of constraint into the  
239 research design - limiting the study. Expanding the search with synonyms to not exclude potentially  
240 relevant articles simultaneously allowed in many irrelevant alternative uses of each term. The  
241 extremely high numbers of search results required careful and time-consuming manual reviews of

242 each article to determine relevance. For this reason, the initial literature base to be searched was  
243 further limited to only include:

- 244 • Peer-reviewed scientific articles – to ensure an equal level of quality and similar academic  
245 intent amongst the work. This limits the search results and introduces a bias to the body of  
246 literature reviewed.
- 247 • Empirical articles based on original research, i.e. no conceptual articles, review articles or  
248 descriptive case studies – to focus the discussion on what outcomes of participation in  
249 relation to green space quality are being tested.
- 250 • Articles in English-language publications, which include the most relevant international  
251 journals while allowing for equal review depth and understanding of the works.
- 252 • Articles referring to user participation in the making or keeping of public urban green spaces  
253 – to distinguish from other definitions, i.e. participation as use of green spaces, or green  
254 spaces not publically accessible within built-up areas.

255 The search was carried out between February and May 2013. The databases Scopus and Web of  
256 Science were chosen for the relatively high standard of research and consistency of peer-reviewed  
257 papers within the results. While these sources were not exhaustive, based on experiences from  
258 earlier reviews these databases can be understood as roughly representative (Konijnendijk van den  
259 Bosch et al., 2013).

260 In Scopus the search string was used under the search category ‘title-abstract-keywords’, and in  
261 Web of Science under ‘Topic’. This yielded an initial 2,940 articles to be reviewed further for  
262 relevancy (1,761 in Scopus and 1,179 in Web of Science, with some overlapping results). The scope of  
263 understanding the different uses of the search terms in fields such as neuroscience and biology led to  
264 the need for excluding journals that do not focus on urban planning, design, or management issues.

265 The closest journals to the study theme excluded during this step were in the fields of atmospheric  
266 environment, wildlife research, medicine and marine areas as well as environmental- and  
267 conservation management. Hit results, particularly from these borderline fields were manually  
268 checked during the journal exclusion process to ensure that potentially relevant articles were not  
269 being lost. The final search returned results from 14 journals in Scopus and 13 journals in Web of  
270 Science (see Fig. 2).

271 Fig. 2 here!

272 After these limitations, the search returned a total of 308 hits, of which 34 were duplicates,  
273 resulting in 274 unique hits to be manually reviewed against the article qualities and topic relevancy  
274 established in the previous sections of this article. This step primarily removed articles not containing  
275 empirical work and then read closer into each study's focus. Special consideration regarding  
276 relevance was made for articles falling within studies of national parks - those not located in cities  
277 were omitted for not qualifying as *urban* green spaces and those evaluating participation by non-  
278 local special interest groups were omitted as not dealing with *user* participation – resulting in  
279 omission of national park studies. Further, a handful of leisure articles were removed from the  
280 review upon finding that their field's definition of participation did not extend beyond actively using  
281 parks and green spaces. Leisure articles that did deal with participation in the making and/or keeping  
282 of green spaces remain in the review. Fig. 2 illustrates the range of field in the search results versus  
283 those finally selected for review.

284 From this step, 26 articles met the review criteria and were read for further review. After the  
285 initial readings, attention turned to the reference lists in a method known as 'snowballing', and five  
286 additional relevant articles were found and reviewed, for a total of 31 articles. While *community*  
287 *garden* was not an original search term due to the special nature of the typology and often lack of  
288 public accessibility, three studies about urban, publically open community gardens were found and  
289 included.

290 **Analysis**

291 The in-depth reviews of the 31 articles began with careful reading and note-taking. A Microsoft Excel  
292 spreadsheet was compiled and used to guide the note-taking and organize information that could  
293 potentially be compared later. The spreadsheet was designed to systematically log each article's  
294 basic publication information, aim(s), methodology, main arguments and findings. Using a grounded  
295 theory approach - where trends apparent in the data material guide further analysis (Denzin and  
296 Lincoln, 2011) - categories were added to the spreadsheet to better sort the logged notes. The  
297 resulting 27 categories are shown in Table 2.

298 Table 2 here!

299           The body of data collected was explored for trends to structure further analysis and  
300 better define the research questions. While the literature review began with the intent to analyse  
301 how participation in green space management affects physical green space quality, i.e. participation  
302 in the keeping of green spaces, the utter lack of articles testing this lead to broader research  
303 questions about how participation in all phases of green space development has been researched.  
304 The ranges of study aim and focus within the body of literature alerted the reviewers of the need to  
305 sort the data by spatial scale, type of participation, and phase in green space development. Trends  
306 and disparities found within sorting the articles thus organized the rest of the analysis. Despite broad  
307 differences in studies, comparisons of the deeper content of the articles were possible – many  
308 researchers drew upon similar arguments to support participation, so focus turned to how those  
309 arguments are used.

310           In order to understand why the effects on the physical green space did not seem to be  
311 in focus in the reviewed articles, Randrup and Persson's model (2009) was adapted into an analytical  
312 framework to chart how participation processes in the literature affected public urban green space,  
313 users and administrators over the two phases of green space development (see Fig. 1). The

314 framework allowed connections to be drawn between participation and green space quality –  
315 counting, comparing and assessing directness between the dimensions. This process emphasized  
316 how administrators, users, and green spaces each hold roles affecting green space quality, potentially  
317 benefiting from participation. Detailed explanations of how the framework was used in conjunction  
318 with the categorized notes from the literature are offered throughout the results section.

319

## 320 **Results**

321 The results of the literature review are introduced here with general characteristics of  
322 the research, followed by sub-sections organized by the three research sub-questions and a summary  
323 section responding to the main research question.

### 324 ***General characteristics of the body of research***

325 The relevant research fields focusing on user participation in urban green spaces help  
326 to explain trends and limits found later in the analysis. Despite limitations imposed on the literature  
327 search, the resulting articles still vary, representing the range of research on participation in urban  
328 green spaces (see Fig. 2). While many articles were deemed irrelevant to the review, a span in field  
329 and topic still remained after their exclusion. Urban forestry is well represented, holding the highest  
330 number of articles within the journal Urban Forestry and Urban Greening.

### 331 Geographical location of studies and year of publication

332 Table 3 lists articles by author, year and study location. These results are mapped in  
333 Fig. 3, using a conventional division into seven continents. An interesting gap was quickly noticed  
334 between the first two articles in the early 1980s and the remainder following after the latter half of  
335 the 1990s – highlighting the topic’s popularity today. In spite of the age of the two early outliers it

336 was decided to include them as they did not stand out in content and were likely precedent for many  
337 of the more recent articles.

338                 Sorting the articles by date and location suggests the topic's popularity beginning in  
339 North America 30 years ago, holding dominance there and in Western Europe, then gaining  
340 publication popularity over the last 10 years from the Asian countries of Taiwan, Nepal and China  
341 (incl. Hong Kong). Despite local context differences, the articles from these four countries all argue  
342 for increased citizen participation rather than reviewing participation processes that have actually  
343 taken place. Along with one article from Russia (Nilsson et al., 2007), these studies hold the strongest  
344 discourse over the ability of participation processes to legitimize government (Huang, 2010; Gurung  
345 et al., 2012; Lo and Jim, 2012; Shan, 2012), potentially signalling a growing interest and support for  
346 participation while Western focuses move towards critique of ongoing processes.

347 Table 3 here!

348 Fig. 3 here!

#### 349 Aims and general focus of the articles

350                 The articles were found to focus upon participation in three different manners that we  
351 categorized as those studying participation processes, those that build a case for potential  
352 participation and those that reflect indirectly over cases after participation has been implemented.  
353 These three focuses are signified by markers (X, O, –) keyed in Fig. 3 and the accompanying Table 3.  
354 Having noted the stated research aim or intent of each article (typically found in an abstract or  
355 introduction section), four themes of research aim were found. These are tabulated in Table 4  
356 against the three general focuses discovered, demonstrating the breadth of the research covered by  
357 the articles. While most study participation processes that are in place, seven of these articles do  
358 not: Kaplan (1980) and Huang (2010) look generally at the perceptions of improved green spaces that  
359 included participation and five others build cases to support potential participation (Crompton et al.,

360 1981; Jansson and Persson, 2010; Gurung et al., 2012; Lo and Jim, 2012; Shan, 2012). Common across  
361 these seven is a strong position regarding how participation could better local green space  
362 administration and perception.

363 Table 4 here!

364

### 365 ***Types of participation and green space development phase***

366 A range in the scale of green spaces studied was also identified. The spatial scale of  
367 the study likely impacts the amount of detail in empirical work; large scale planning studies in  
368 particular lacked specific connections between participation outputs and green space quality. The  
369 large scale studies of regions or country comparisons also neglected to discuss the green spaces in  
370 detail, while articles with city or site-specific cases described green spaces in analytical or descriptive  
371 manners.

372 Table 5 here!

### 373 Types of participation findings

374 To understand how the different types of participation (see Table 1 for examples) are  
375 treated in research across different spatial scales, articles were tallied and compared according to  
376 these parameters (see Table 5). Results indicated that physical participation studies were more likely  
377 on the site-specific scales of green spaces, as participating physically implies that users are present in  
378 a specific space. This finding was in line with our original assumption. However, this review also  
379 found reference to how physical participation is influenced remotely by e.g. national or regional  
380 policies and demographic trends (Straka et al., 2005; Wall et al., 2006).

381 On the other hand, civic participation - which can take place at any spatial scale – was  
382 the type most studied. This emphasis on civic participation likely reflects increased governmental and  
383 international research priorities concerning participation, but also reinforces the research question of

384 this review, questioning whether specific physical outcomes of participation processes are being  
385 analysed.

### 386 Green space phase findings

387 As described in the Definitions subsection of this article, both civic and physical  
388 participation can be employed in either the making or keeping of a green space. Cross-analysing the  
389 review results across phase and participation type finds a fairly balanced overall division of making  
390 and keeping, but far more civic participation studies in the making phase (see Table 6).

391 Table 6 here!

392 The articles that included both types of participation were predominantly local studies of friends  
393 groups (Jones, 2002; Jones, 2002b) and community gardens (Glover et al., 2005; Rosol, 2010; Bendt  
394 et al., 2013) where the green space users have taken on nearly all roles and responsibilities within  
395 green space management - acting in the visioning, lobbying, marketing and funding of spaces as well  
396 as within daily maintenance.

397

### 398 ***Arguments for participation and green space development dimension impacted***

399 To answer the second sub-question of this review, the analysis turned to the rhetoric  
400 used to support participation in connection with the green space development dimensions  
401 benefited. Given the diversity of the articles, it was not surprising to find an array of support and  
402 potential benefits attributed to participation. These arguments (termed “arguments for  
403 participation” are listed in full in Table 7) were predominantly found in the introductions and  
404 conclusions of the articles, largely discussed through cited literature including a wide body of both  
405 academic and governmental reports.

406 Identified arguments for participation

407 This list of arguments include social goals such as consensus and community building,  
408 as well as natural science objectives like increased number of trees – demonstrating an  
409 interdisciplinary range that would likely require blending quantitative and qualitative research  
410 traditions if united for empirical study. The range reemphasizes the many actors and diverse  
411 priorities involved in participation processes and the subjectivity of concepts such as *success* and  
412 *green space quality*. Many vague expressions were found in the arguments without clear definitions,  
413 but in the cases these were operationalized, each defined sub-argument appears as a separate line in  
414 Table 7. The ambiguous arguments for participation are tallied separately, finding amongst the most  
415 common: ‘better governance processes’, ‘better and more effective green space administration’, and  
416 ‘improving green space quality’. All three of these arguments again contain variation regarding  
417 actors, priorities, and perspectives.

418 Table 7 here!

419 Dimension of green space development served

420 Each found argument can be understood as primarily serving or impacting one or a  
421 combination of the dimensions from the framework (*users, administration or public urban green*  
422 *space*). Fig. 4 diagrams and tallies the arguments thus.

423 Fig. 4 here

424 Since many of these arguments borrow from different academic traditions (including  
425 environmental psychology and political science) and focus on different framework dimensions, the  
426 arguments that are directly linked to green spaces were of primary interest in this review. These  
427 included ‘increased green area’, ‘increased number of trees’, ‘improved functionality’, and ‘healthier  
428 trees’, all of which are testable, physical aspects which could contribute to an understanding of green  
429 space quality. The arguments ‘better appearance’ and ‘higher quality’ are again vague and require  
430 clear operationalization to be empirically tested.

431                   However, users and administrators may also affect green spaces indirectly, so  
432 arguments along the vectors from users and administration were also of interest in their potential to  
433 affect physical green space quality. Arguments such as ‘better decisions’ and ‘creative solutions’ for  
434 example can contribute to physical green space quality and be subjectively assessed. Before and  
435 after studies are likely needed to empirically examine ‘better and more effective green space  
436 administration’ and to understand whether ‘user satisfaction’, ‘attachment’ and ‘ownership’ can be  
437 attributed to the participation process itself or to the access of a high quality green space, or a  
438 mixture of the two. The studies which focused on these aspects did not survey the same users who  
439 participated in park up-gradations; they rather made cases for green space attachment and the  
440 benefits of up-gradation in general rather than remarking solidly on the participation processes  
441 (Kaplan, 1980; Huang, 2010).

#### 442 ***Empirical evidence linking participation to green space quality***

443                   The third sub-question led the review to compare rhetoric of participation with what  
444 was empirically tested in the articles. Of the many arguments for participation discussed in the  
445 literature, rather few instances of the arguments being empirically tested were found (see Fig. 4).  
446 Table 7 tabulates the number of discussed vs. empirically tested arguments in addition to sorting  
447 them by green space phase. An equally large disparity was found in empirically tested arguments  
448 from the two phases of green space, and likewise when the arguments were sorted in regard to  
449 requiring qualitative or quantitative methods, demonstrating an even and general lack of thorough  
450 testing verses rhetoric. Part of this may be attributed to the difficulty of testing very subjective  
451 notions, but it also implies that many tenets and benefits of participation are taken for granted.  
452 Participation to date remains little tested against physical outputs for green spaces.

453                   In particular, the arguments most directly linked to the green spaces were least tested  
454 in regards to number discussed – only the notion of healthier trees was tested, and that only in one

455 article. Nannini's (1998) study was not only site specific, but also limited to user participation in tree  
456 surveying and maintenance work to prevent Dutch Elm disease. The specific nature of the research  
457 question allowed a direct, empirical before-and-after study that showed how increased attention and  
458 data made possible by user – in this case resident – volunteer participation was successful in  
459 increasing the overall health of the trees, stopping the spread of the disease.

460           Along the vectors pointed towards public urban green space, a few less direct, but  
461 tested benefits to green spaces were found. Through considering implemented information from  
462 participation practices, Buizer and Van Herzele (2012) and Van Herzele (2004) demonstrated better  
463 and more creative solutions in master- and park planning. Bloniarz and Ryan (1996), Nannini et al.  
464 (1998), and Conway et al. (2011) found benefits to green space management through users' physical  
465 participation. Several articles also demonstrated increased usage after participation processes, often  
466 in correlation with increased satisfaction (Kaplan, 1980; Jones, 2002b; Glover et al., 2005; Huang,  
467 2010). These were deemed as indirect or secondary relations to green spaces due to first benefiting  
468 the processes or actors over necessarily ensuring physical green space quality. While the finding of  
469 increased usage and satisfaction demonstrates user perception of quality or improvement, it could in  
470 fact detract from physical quality and result in greater maintenance needs for green spaces due to  
471 e.g. intense trampling and increased wear and tear.

### 472 ***Reflection of research over user participation's contribution to physical green space*** 473 ***quality***

474           Several tested and generally supported arguments for using participatory practices can  
475 be found which may be indirectly important to physical green space quality. Personal benefits that  
476 users get from the act of participating (e.g. Still and Gerhold, 1997; Townsend, 2006; Wall et al.,  
477 2006) and those benefits the administration of such processes receives in terms of input and  
478 affectivity (e.g. Sipilä and Tyrväinen, 2005; Rosol, 2010; Buizer and Van Herzele, 2012) are not to be

479 overlooked. It may be possible on a case-specific basis to trace the benefits of human actors to the  
480 green space along the model and find that, for example, legitimacy in government and strong user  
481 voices can lead to better green space administration which in turn improves the physical quality of a  
482 green space. However, such connections were rarely detailed empirically in the reviewed literature,  
483 and the considerable focus on testing human actor benefits could be worrisome, particularly in the  
484 interest of physical green space quality.

485                   Finally, when analysing the results and conclusions sections of the reviewed articles  
486 for reasons that specific participation programs were unsuccessful or suffer, the following reasons  
487 were found (number of article mentions in parentheses after each): professional scepticism (8),  
488 communication (6), varying personal interest in vegetation (5), commitment (both ways - 5), little  
489 government support / tokenism (3), no trust in government (3), uneven levels of activity (1), funding  
490 (1), conflicting interests (1) and lacking implementation (1). These demonstrate several  
491 contradictions to the general, particularly untested rhetoric found amongst the arguments for  
492 participation. Many of the studies about physical participation found that it cannot be relied upon for  
493 the long term without the support of municipal administrators because of participant inconsistencies  
494 - people lose interest, get busy, or motivation fades after start-up (Jones, 2002b; Young, 2011). While  
495 individual interest in participation processes may spike in the short term, meaningful participation  
496 for green space maintenance and improvement needs to be long-sighted and consistent (Ibid.).

497

## 498 **Discussion**

499                   The gaps found within the empirical testing leaves the subject open to question,  
500 particularly in terms of the physical and environmental outcomes of participation in green spaces.  
501 Despite environmental focuses in green space rhetoric throughout sustainable urban planning goals,  
502 few studies from this review empirically considered the direct effects of participation upon physical

503 green space quality. The overall range of empirical focus primarily represents inconsistency –  
504 confirming a general dis-census of intentions, goals and outputs of participation.

505 In terms of more subjectively assessed quality, improvements in user perception of  
506 green spaces were represented and tested in several articles. The act of participating in decision  
507 making can lead to physical outcomes better reflecting user preferences, though simply being  
508 involved may also lead to increased satisfaction – therefore satisfaction is not necessarily linked to  
509 improvements to the green space. Furthermore, other acts of updating, rehabilitating, or improving a  
510 space, not connected to participation, can result in increased satisfaction, so proof of participation’s  
511 specific role remains somewhat at large.

512 Regardless of one’s definition of green space quality, the inconsistencies represented  
513 in the research provide little evidence to combat scepticism towards participation in green space  
514 development. Many professionals are in disagreement over the benefits of participation, how to  
515 implement it, and how to make it effective. Research shows that administrative actors are hesitating  
516 to involve users in green space management due to worries about the impact of such processes on  
517 the quality of the green spaces (Molin and Konijnendijk van den Bosch, 2014). Further, research on  
518 local participation efforts often points to a relationship between participation processes and output  
519 in terms of retaining members, due to participants being motivated by the perception of the physical  
520 outcomes of their efforts (Rydin and Pennington, 2000; Speller and Ravenscroft, 2005; Young, 2011).  
521 However, without an understanding of how participation might directly affect physical green space  
522 quality, debates continue. Empirical research can evaluate and test rhetorical premises of  
523 participation against contextual and case-based outcomes – but researchers must be cautious of  
524 which aspects of participation are taken for granted.

525

526 ***Prior assumptions vs. review study findings***

527                   A number of assumptions were overturned and confirmed during this review. Under  
528 sub-question A, the initial assumption was that physical participation may be the most clearly and  
529 directly traceable type to physical green space quality. Civic participation was not overlooked and the  
530 surprising majority of articles handling it, not only guided its inclusion for analysis, but also  
531 reemphasized a focus on process rather than green space quality outputs. Several benefits that  
532 influence green spaces indirectly were demonstrated, but the empirical studies were dominated by  
533 user or administrator benefits from participation. This is likely influenced by long-running research  
534 traditions behind governance that link participation to human benefits with scholars such as Elinor  
535 Ostrom and Patsy Healy (Smith et al., 2014) having built upon Arnstein's (1969) work. The process-  
536 focus further likely reflects upon available research funding, stemming from process-focused national  
537 policies. Such policies, for example Local Agenda 21 plans which are derived from the Agenda 21  
538 Action Plan drawn up by the United Nations Conference on Environment and Development (UNCED,  
539 1992), promote strategic user inclusion in environmental planning processes, but remain open to  
540 critique regarding influence on plan content or end products (Selman, 1998).

541                   In line with this lack of concrete output focus in participation, theoretical concepts  
542 such as Collaborative Planning (Healey, 1997) and Network Governance (Hajer and Wagenaar, 2003)  
543 have largely guided western urban planning in research and practice over the past decades  
544 (Sehested, 2009). These too reinforce a priority on process and governance, often over process  
545 outputs – the actualities of which are sometimes quite distant from theoretical intentions (Fainstein,  
546 2009). Despite critique, these international, process-focused mind-sets support the high number of  
547 articles focused upon civic participation particularly in the making phase of green spaces and the lack  
548 of articles representing physical participation in this phase. The research overlooked physical, making  
549 participation - users building green spaces for example.

550                   The articles from this review that did focus on physical participation and physical  
551 outputs often related to green space management, which is a field where technocratic, instrumental,

552 and expert dominated approaches traditionally have prevailed (de Magalhães and Carmona, 2008;  
553 Randrup and Persson, 2009; Sehested, 2009; Dempsey and Burton, 2012). Physical participation-  
554 oriented articles often followed a discourse of local governments employing particularly voluntary,  
555 physical participation to streamline resource use. Further, bureaucracy, inefficiency, and stress on  
556 public budgets often push local governments to distribute more responsibility to local communities.  
557 This is evident in countries taking precedent from England, for example, where the conservative  
558 government's 'Big Society Manifesto' points at increased localism in budget allocation between  
559 public services such as libraries, street cleaning and green spaces (Kisby, 2010). When money is not  
560 allocated for green space maintenance staff, local authorities are forced to seek external and  
561 community partnerships as a way to sustain service delivery (Mathers et al., 2011). In this review,  
562 Young (2011) also studied funding issues across different types of tree planting initiatives, finding  
563 underfunded grassroots projects that work in the short term, but inconsistency in the ability to  
564 sustain them without municipal funding and effort.

#### 565 Impacts to green spaces rarely empirically tested

566 Sub-question B questioned if arguments for participation actually serve green spaces.  
567 Tabulating the different arguments for participation demonstrated how few of the arguments  
568 directly impact green spaces. Instead, the aspects of participation benefiting user and administrative  
569 actors align with a traditional human-centric and government-down approach to green space  
570 administration. Review results show that participation in urban green space development is still  
571 being considered as going from users, through an administrative body and then being implemented  
572 at the green space, rather than directly from users to green space.

573 Many of the physical participation processes evaluated did look at programs where  
574 users have a direct influence over the green space – in planting or monitoring vegetation for  
575 example. Success of some of these programs was attributed to the relationship between participants  
576 and the administrators of the participation processes. Many articles noted that user participation

577 alone cannot sustain itself, reminiscent of Swyngedouw's (2005) and others' critiques of the  
578 Neoliberal tendency to shift responsibility from governmental actors to civil society and the private  
579 sector. Questions follow from this regarding who represents the long-term user needs in green  
580 spaces, who safeguards public interest, and who regulates the careful balance between urban use  
581 and environmental values (Ibid.).

582                   Although research over physical participation practices was limited in the reviewed  
583 studies, more case-specific studies have been extensively described in 'grey' literature (e.g. Dunnett  
584 et al., 2002; Van Herzele and Denutte, 2003; Van Herzele et al., 2005; CABE, 2010; Center for Park og  
585 Natur, 2010; Mathers et al., 2011). These more 'hands on' and local studies are often commissioned  
586 by local or national government bodies. While these reports are of great value for the field and cover  
587 the context-dependent nature of most problems, they pose a challenge to knowledge sharing due to  
588 their limited distribution and lack of peer review. Additionally, the idea of being physically engaged in  
589 urban green spaces is in line with popular trends such as Guerrilla Gardening (e.g.Tracey, 2007) and  
590 Urban Agriculture (e.g. Bhatt et al., 2008), which are typically user-based activities performed  
591 without formal mandate, leaving them potentially less researched than more formalized processes.

#### 592 Need for case-specific, holistic empirical studies

593                   Answering research sub-question C demonstrated a surprising amount of rhetoric  
594 about participation being employed by researchers with little clear questioning or empirical support.  
595 The review began with a question over whether participation outputs are tested directly in regard to  
596 physical green space quality, but the findings showed a generally low percentage of testing of  
597 participation outcomes benefiting users and administration as well. This trend can be related to  
598 broadly accepted understandings of participation's purposes, implementations, and end goals that  
599 have also plagued fields like communicative planning for many years (Fainstein, 2009). Empirical  
600 studies could take a more active role in clarifying misconceptions and testing mechanisms that might

601 relate or defeat generalizations within specific contexts, better informing how participation  
602 implementations in different development phases can most effectively better green spaces.

603           The generalizations of this review are likely connected to the considerable number of  
604 large scale (city, state, national) studies which are simply too large in scope to evaluate place-specific  
605 results. The gap in scientific knowledge calls for a re-focus of research to the case level in order to  
606 approach a better understanding of the specific green space quality outcomes of user participation.  
607 Research could focus upon what civic and physical participation processes contribute to physical  
608 green space quality and how they most effectively can be employed. A new generation of research  
609 could clarify much of the debate found here.

610

### 611 ***Methodological reflections***

612           In this study, an adaption to Randrup and Persson's (2009) park-organisation-user  
613 model served as analytical framework to structure the literature review around dimensions of green  
614 space development. In the literature, only two arguments for participation were found that  
615 supported part of the model's adaptation – namely the vector added to directly link *users* to *public*  
616 *urban green spaces*. Articles focusing on physical participation link the users to green spaces in  
617 action, but the potential benefits of participation along that vector remain little explored. Otherwise,  
618 the framework allowed a holistic approach to considering green space administration and could  
619 methodologically serve further research. It was particularly useful in the illustration of gaps and  
620 biases considering the different dimensions and their potential direct and indirect interactions. In Fig.  
621 5, the diagram is used to illustrate the demonstrated need for additional research focus from human  
622 actors to the green spaces.

623 Fig. 5 here!

624 Limitations of this review

625           This study, with the intent of getting an overview of the research field, benefited from  
626 the search being initially unrestricted in terms of participation types and spatial scale of study.  
627 However, this open process led to broad ranges in results which could be problematic for more  
628 specific research questions. In terms of a review and the field of research, the body of excluded  
629 research remains substantial and is open to future review studies with different green spaces in focus  
630 - national parks or community gardens for example. The urban focus of this review disregarded  
631 studies about user participation in the fields of natural resource management, nature conservation,  
632 non-urban forest planning which could likewise be branches for further study and cross-comparison.  
633 Studies from these broader fields are likely to demonstrate even more approaches to, applications  
634 and goals of participation. The review's focus on articles written in English may have affected the  
635 geographic distribution of found participation cases with a predominance of studies performed in  
636 North America.

637

638 **Conclusions**

639           This review focused on peer reviewed research over participation in public urban  
640 green spaces, and found that the empirical work to date has primarily focused on benefits to users  
641 and administrators rather than physical outputs of participation. The overall focus on the  
642 administrative and process-oriented aspects of participation was found to overshadow research's  
643 potential to critique and understand the physical outcomes of participation in public urban green  
644 space development. A great deal of vague rhetoric about wide-ranging benefits of participation was  
645 found to be employed without empirically testing against reality in specific contexts.

646           In particular, this review found very little empirical evidence of direct links between  
647 participation and the physical quality of green spaces, i.e. how the green space performs  
648 environmentally and meets local needs for use. Importantly, the impact on physical green space

649 quality from user participation in maintenance tasks remains hopeful but little tested across the  
650 reviewed studies. User participation activities should be developed and tested against the practical  
651 needs of green space development in order to improve physical green space quality. A prerequisite  
652 for such empirical testing is a clear definition of green space quality, adjustable to suit each individual  
653 place, to determine what features of the green space that should be assessed as well as whether  
654 subjective and/or objective assessments should be carried out. Reflective research could then  
655 contribute to proving where the actual benefits of participation lie in practice, and how participation  
656 processes can be most meaningful. In this manner, research could better inform administrators in  
657 what to realistically expect from participation exercised in different points of green space  
658 development.

659           While it is implicitly agreed that participation is good and capable of improving green  
660 spaces, more proof is needed to understand the mechanisms by which participation affects physical  
661 green space quality. Most studies to date have been process-driven rather than product-driven,  
662 despite drawing upon an abundance of green space quality rhetoric. While participatory processes  
663 are widely demonstrated to improve civic relationships and trust in government, little research  
664 empirically connects those processes to physical outcomes. Without a body of empirical evidence  
665 linking participation to green space quality, neoliberalism critique and professionals' scepticism can  
666 continue without response. Despite agreement over the great importance of providing high quality  
667 green spaces in urban areas, it remains unclear whether participation actually improves parks, or if it  
668 is exercised just for the benefit of the people involved?

669

## 670 **Acknowledgements**

671                   The authors would like to thank the three anonymous reviewers for their constructive  
672 comments during the process of developing this article. This review article was partly funded by the  
673 project Urban Transition Öresund Interreg IVA. The authors are grateful for this support.

875 **Figure legend**

876 Figure 1. Analytical framework for understanding participation in green space development through  
877 actors and dimensions impacted.

878 Figure 2. Journals and Academic fields represented in the search vs. final results. N.B. that the Journal  
879 of Arboriculture was renamed into Arboriculture and Urban Forestry in 2005.

880 Figure 3. Map of geographical location of studies performed in the reviewed articles.

881 Figure 4. Arguments for participation by dimension of green space development. Each argument is  
882 placed by the dimension of green space development it affects most directly. The numbers reflect  
883 how many articles discussed each argument. Numbers in brackets show number of articles that has  
884 tested each argument empirically. In argument, a predominance of possible benefits to urban green  
885 spaces was discussed in the reviewed literature, while a particularly low number of articles tested  
886 direct benefits to urban green spaces empirically. This shows the large disparity between what was  
887 tested and what was discussed from the arguments.

888 Figure 5. Analytical framework illustrating potential focuses to cover the gap in knowledge found in  
889 this article. Direct and indirect connections and their potentials are represented here with vectors.

890

891 **Table legend**

892 Table 1. Types of participation over phases of green space.

893 Table 2. Categories according to which the data from the reviewed articles was organized.

894 Table 3. Reviewed articles listed by author, year and study location. The “Key” column here

895 corresponds to markers in Fig. 3, where X denotes studying participation processes; O articles build

896 cases for potential participation; and – reflects indirectly over cases after participation has been

897 implemented. See sub-section “Aims and general focus of the articles” for elaboration.

898 Table 4. Central aims of study in reviewed articles, organized by general focus marked as X, O and –.

899 X denotes studying participation processes; O articles build cases for potential participation; and –

900 reflects indirectly over cases after participation has been implemented. Markers X, O, and – can be

901 keyed to Fig. 3 and Table 3 above.

902 Table 5. Scale of green space studied vs. type of participation.

903 Table 6. Articles sorted by type of participation vs. phase of green space.

904 Table 7. Arguments for participation with number of instances discussed and empirically tested.

~ multi-city studies

Table 4

<i>aim of study</i>	X Studying Participation Processes	O Case for Potential Participation	- Reflect Indirectly After Participation	Totals	<i>author</i>
Study participation within governance practices (including perception of administrators towards participation).	7	2		9	Konijnendijk, Janse and Konijnendijk, Crompton et al., Jones (a), Sipilä and Tyrväinen, Buizer and Van Herzele, Ricard and Bloniarz, Young, Rosol
Study output of participation (including how much influence participants had, physical results, cost savings, perceptions after participation).	9			9	Van Herzele, Heintzman, Bloniarz and Ryan, Nannini et al., Conway et al., Nilsson et al., Parkin et al., Bendt et al., Glover et al.
Study motivation and character of participants (or potential participation).	5	1		6	Wall et al., Still and Gerhold, Straka et al., Townsend, Shan, Fleming et al.
Study green space perception (relationship between participants and parks).	1	4	2	7	Kaplan, Huang, Lo and Jim, Gurung et al., Jansson and Persson, Sanesi and Chiarello, Jones (b)

Table 5

Scale of Green space:		parks, individual cases	trees, city level	urban forestry, city level	urban forestry, state/national level	green planning, state/national level
<u>Type of Participation</u>		11	6	6	3	5
Civic	15	5	1	4	1	4
Physical	9	3	5		1	
Both	7	3		2	1	1

<b>Making</b>	11		1
<b>Keeping</b>	4	9	6
<b>Total</b>	15	9	7

Table 7

<b>Argument for participation</b>	<b>Discussed</b>	<b>Empirically tested</b>
<b>TOTAL</b>	<b>112</b>	<b>35</b>
<i>Making phase</i>	46	16
Consensus building, settling differences and building community	9	2
Bringing different viewpoints to the surface	1	2
Fostering local knowledge and learning	7	3
Use of existing local knowledge	5	2
Empowerment, increasing people's desire to participate	7	3
Increase number of participants in civic participation	2	0
Increase influence of civic participation	2	3
Resolve lack of trust in government, increase legitimacy	6	0
Better governance processes	7	1
<i>Keeping Phase</i>	66	19
Increased area of green spaces/number of trees	2	0
Higher quality of green spaces	8	0
Increased functionality/suitability to users	7	0
Better appearance of green spaces	4	0
Healthier trees	4	1
Better decisions and more creative solutions	5	2
Better people's perception and satisfaction of the green spaces	4	3
Reduce costs, economical savings through labour and resources	5	1

Better/More effective green space administration	9	3
Increased usage of green spaces	0	4
Boost environmental awareness and human-nature relationships	3	3
Increase attachment and sense of ownership to the projects	6	0
Opportunity for income for impoverished communities	1	0
Improve quality of life	1	0
Enhance technical skills	1	1
More users engage in physical participation	4	0
Increased influence of physical participation	2	1
